Meteorologie und
Geodynamik

Outline

- Introduction
- DC waveform stacking method
- Needs for Antelope
- Outlook

Earthquakes located in Austria since 1900

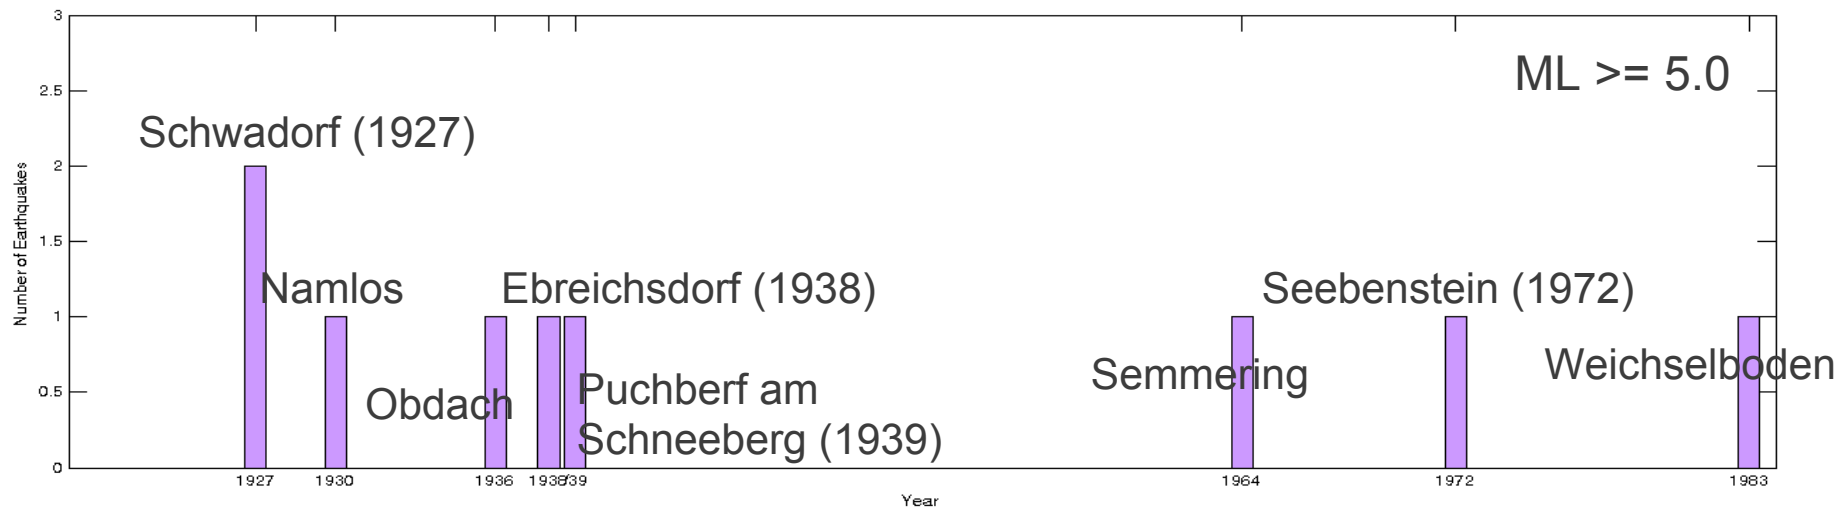

- Over 9000 earthquakes located in Austria and recorded at the ZAMG since 1900.
- Seismic hazard map indicate a_h up to 1.2 m/s^2 (10%, 475 year return period)

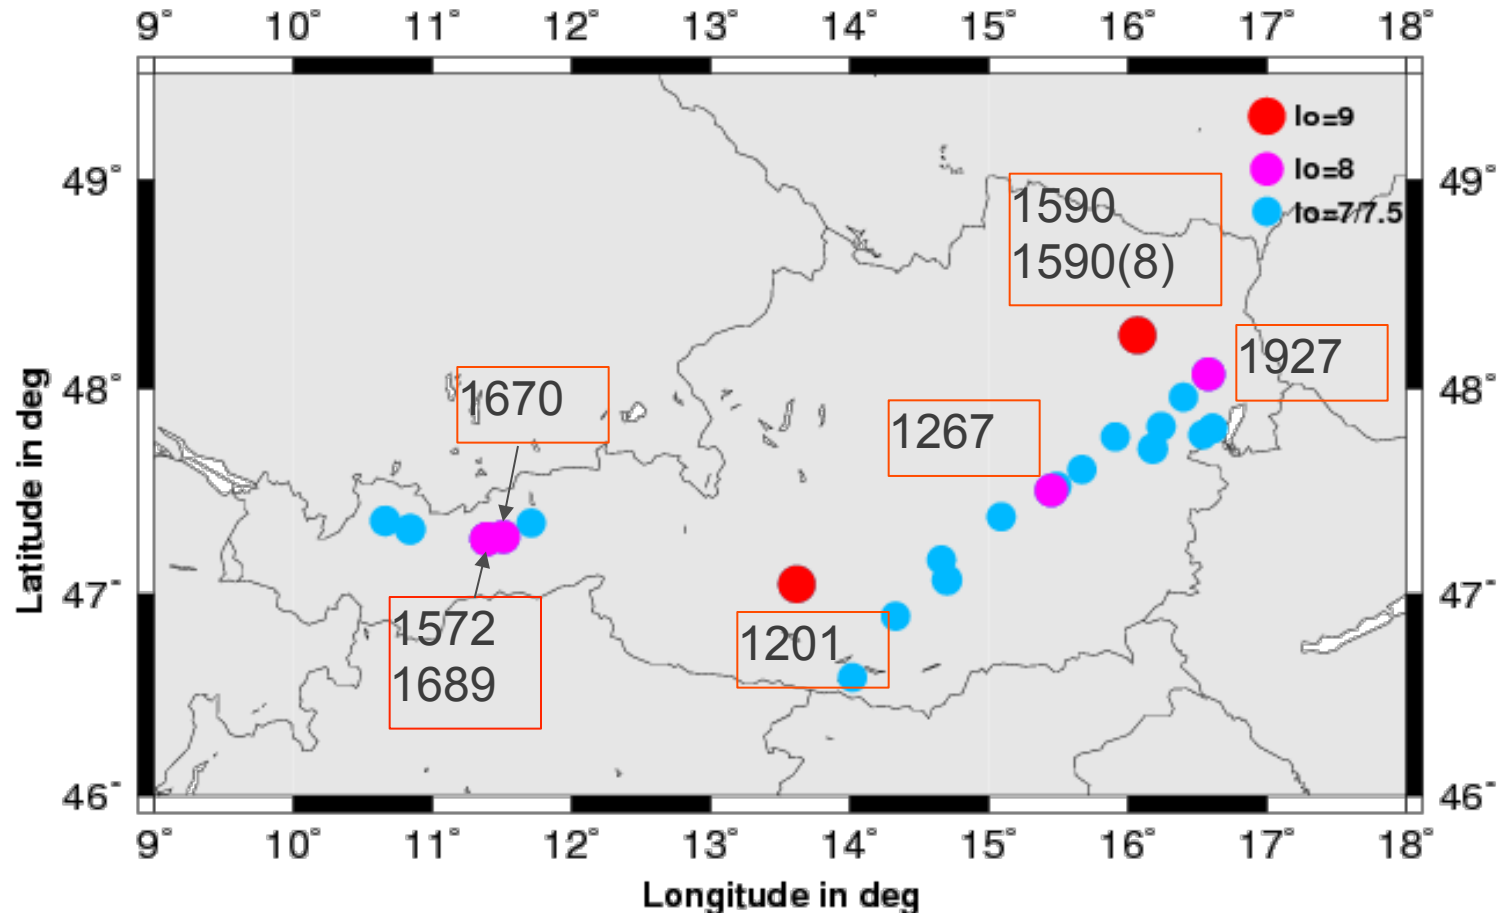

Significant Earthquakes in Austria since 1900

5/28/14

Folie 7

Historic Earthquakes with Heavy Damages

$I_o=9$

1201 Katschberg
1590 Ried/Riederberg

$I_o=8$

1267 Kindberg
1572 Innsbruck
1590 Ried/Riederberg

1670 Hall in Tyrol
1689 Innsbruck
1927 Schwadorf

Moment Tensor Inversion

Radiation pattern

Focal mechanism

Waveform matching, GF's

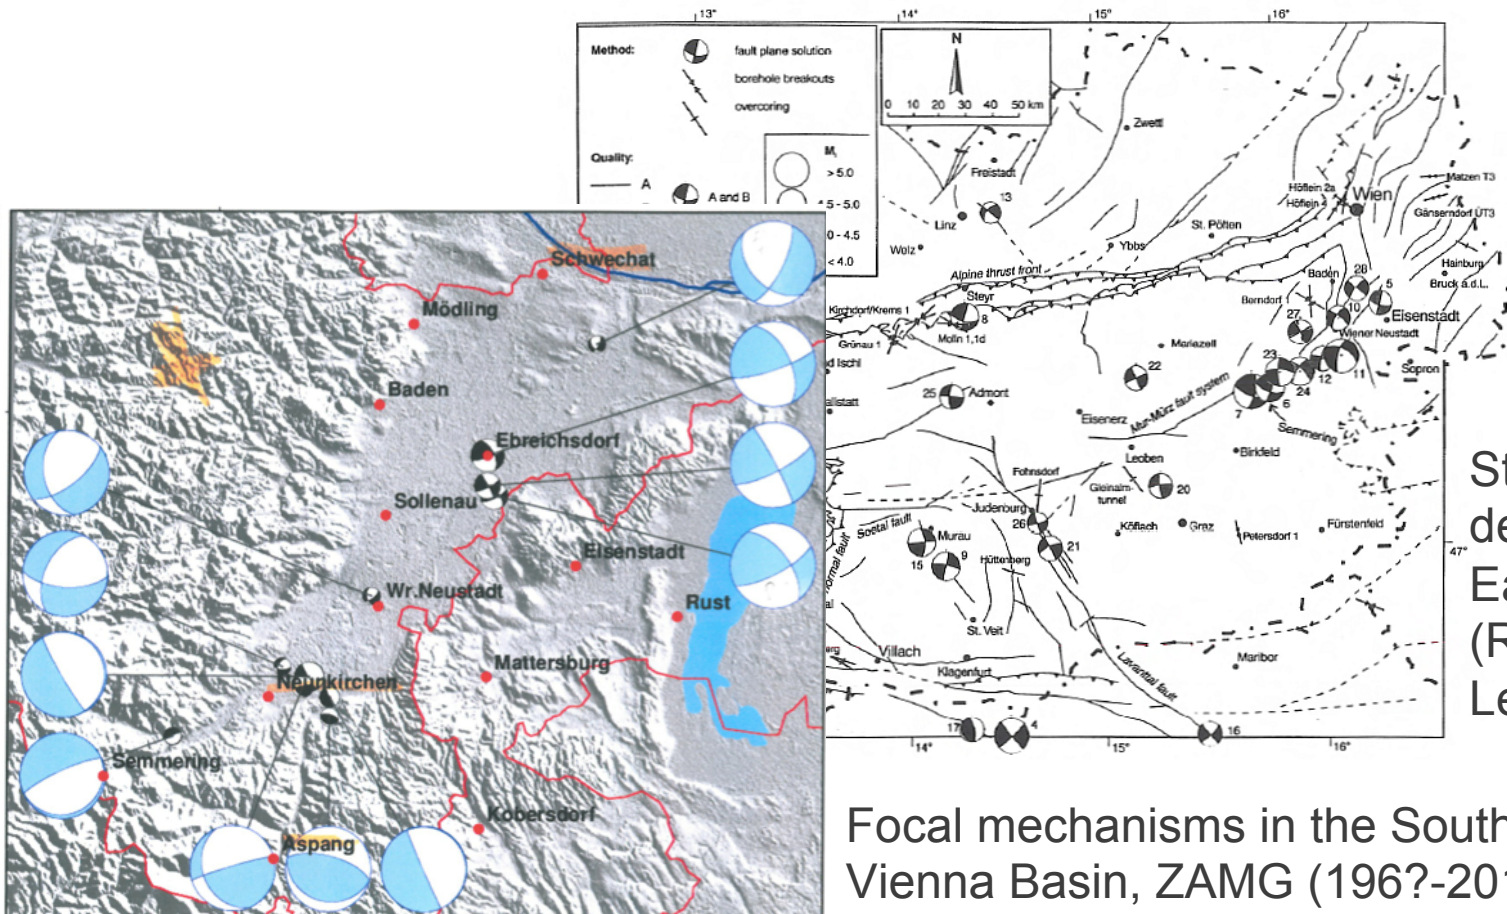

First motion polarity analysis'

- Methods: waveform matching, first motion polarity analysis
- Applications:
 - USGS MI > 5.5
 - ETH MI > 4.5
 - Stich et al. (2003) MI > 3.5

- Problems for regions like Austria: waveform matching (Dreger & Helmberger, 1993) not really applicable, first polarity analysis biased by subjective interpretation of the first motions

Previous studies on focal mechanism in Austria

- since 1965 first motion polarity analysis (F.Reiter, FPS):
- about 110 events (60 with $M_l > 3$)

Stress field and deformation in the Eastern Alps (Reinecker & Lenhardt, 1999)

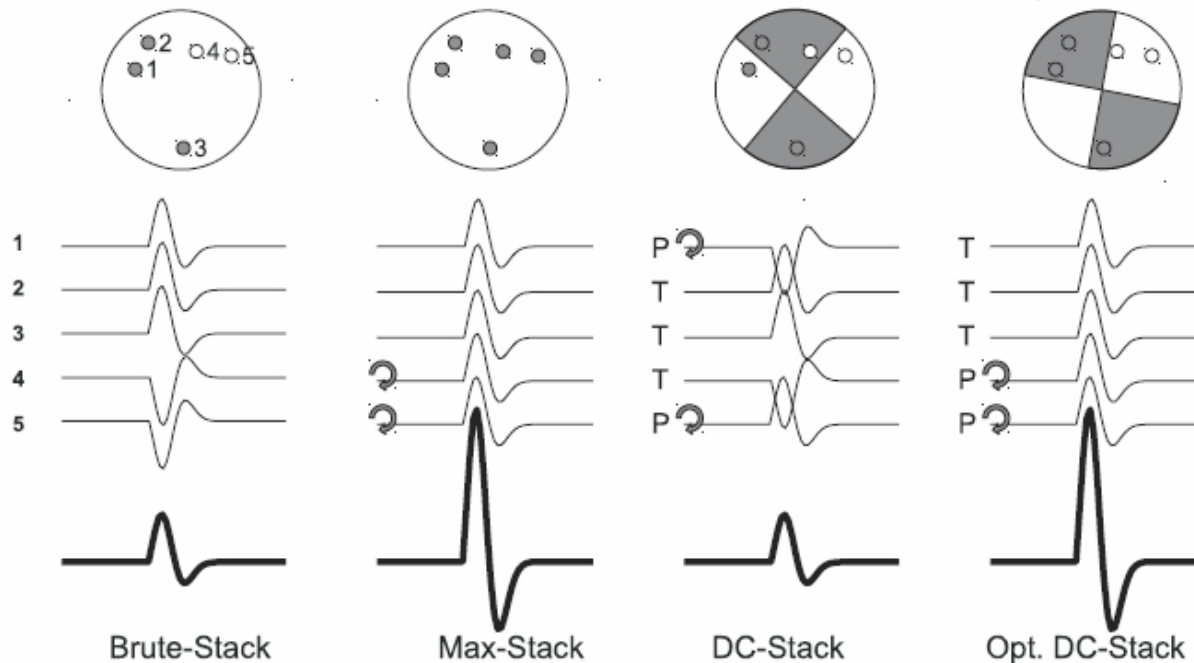

Focal mechanisms in the Southern Vienna Basin, ZAMG (196?-2013)

Aims

- Apply an objective method to increase knowledge on focal mechanisms in the Eastern Alps
 - Compute reliable focal mechanisms for a region with moderate seismicity ($M_I=2.5$ and up) and for signals with low S/N ratio
 - Use a (semi-automatic) algorithm in daily routine work; use pre-existing db (CSS3.0) & waveform access structure from Antelope 5.3+
- >> apply DC waveform stacking method developed during the ALPAACT project from our partner at the Institute of Geodesy and Geophysics (Vienna University of Technology)

DC waveform stacking method

- Double-couple (DC) inversion with P-,SH-, SV polarities (isotrop medium)
- Method was introduced by Weginger & Brückl, 2014 (EGU)
- Available source code in Matlab (GNU GPL)

Weginger & Brückl, 2014

Objective function, Grid Search

Objective Function (OF) -> max!

Weighting: S/N, distance to nodal plane

Weginger & Brückl, 2014

$$OF = (F1_{stack} - F2_{stack}) * Semblance_{stack}$$

Global grid search for Opt. DC stack:

1. Euler rotations for T- and P-Axis > theoretical radiation pattern and polarities
2. Re-orientation of polarities
3. Stacking, Semblance, OF

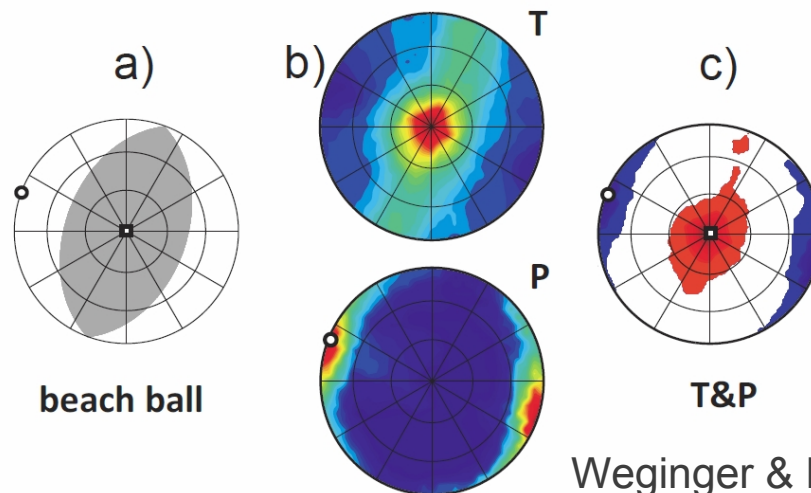

Result and Presentation

- T- and P- axis
- Orientation of focal and auxiliary plane(strike,dip,rake/slip)

a) Beach ball

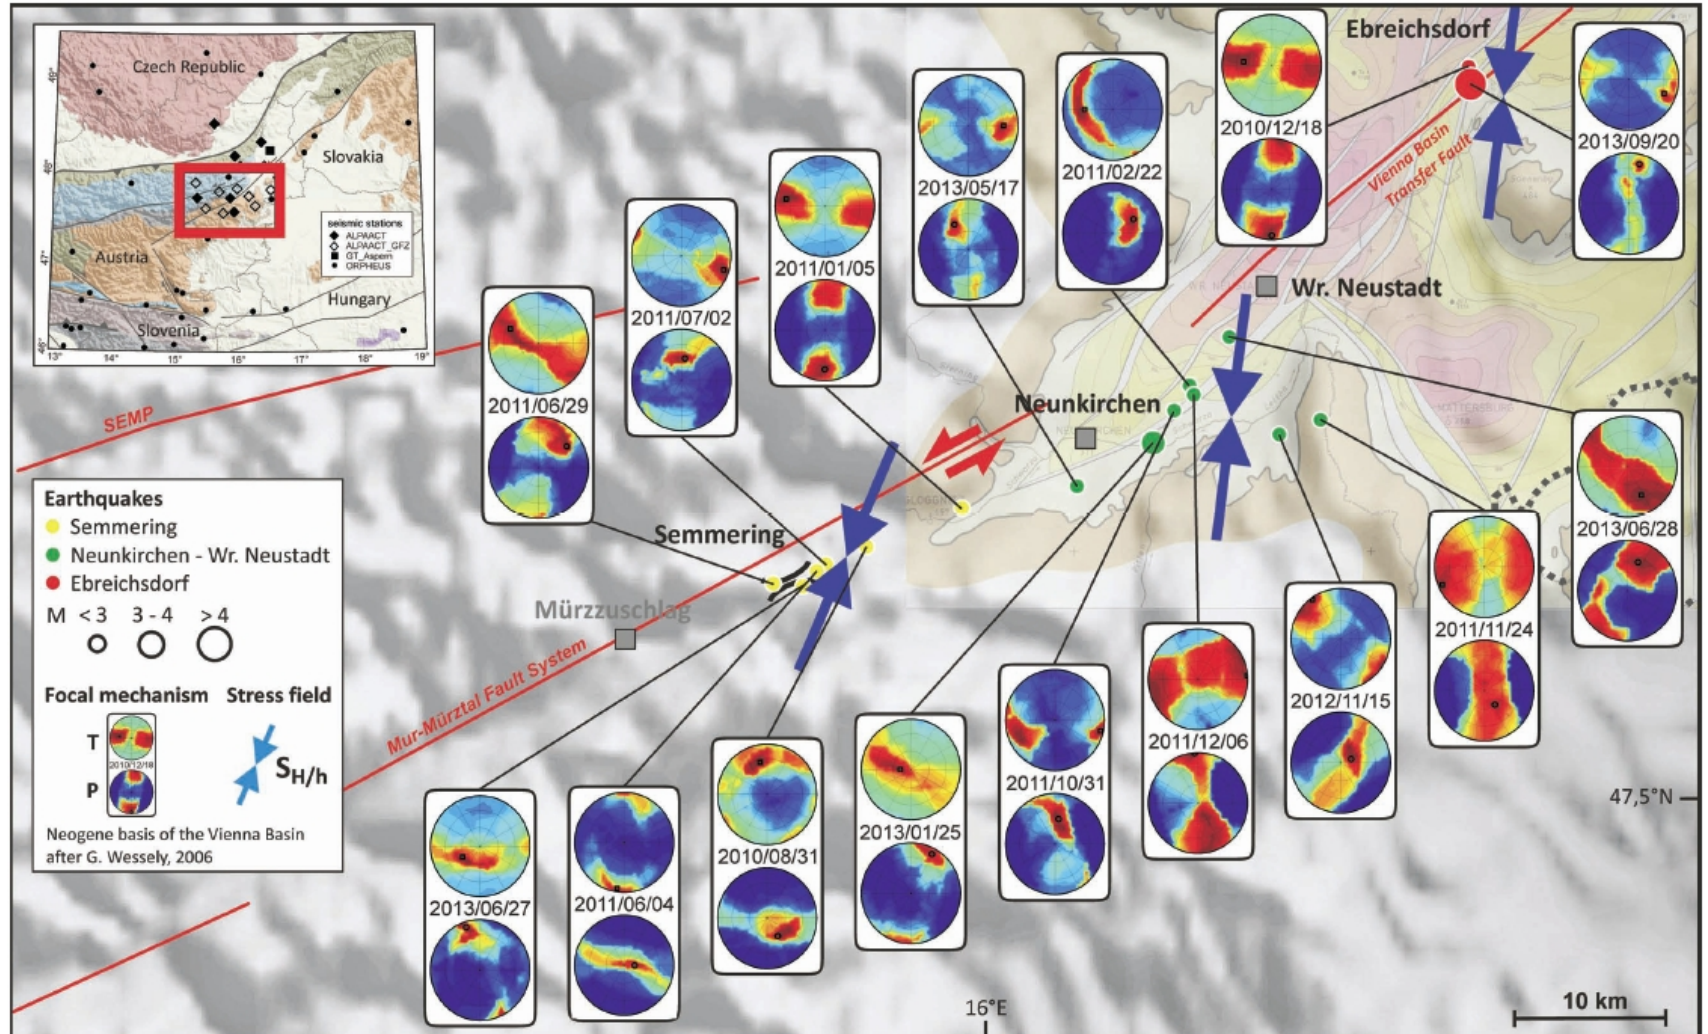

b) T-, and P- Axis separated (good inspection of whole solution space)

c) T-, and P- Axis combined

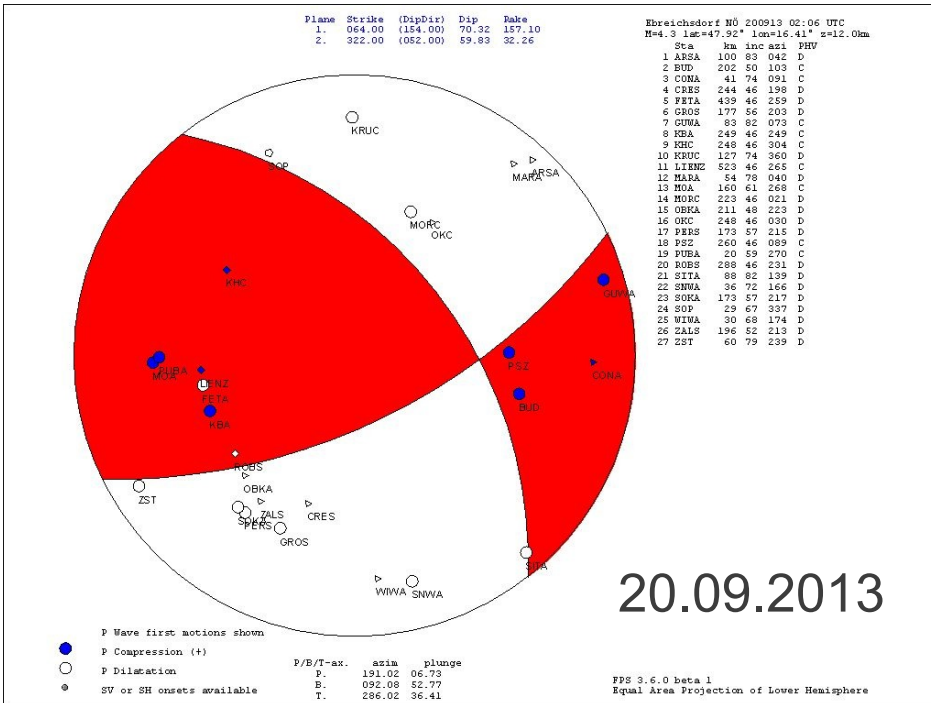

Weginger & Brückl, 2014

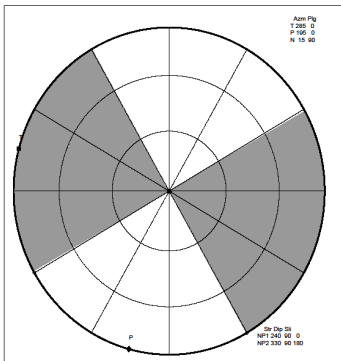

Examples from Real Data (Vienna Basin)

Example Comparison

- $M=4.2$ event located close to Ebreichsdorf (Vienna Basin) on September, 20th, 2013
- Depth=12km
- $I_0=5-6^\circ$ (EMS-98)

Needs for Antelope

Missing

- Unaffected picking of polarities (e.g. display envelope, energy, ..)
- Take off angles for azimuth and dip at the hypocenter
- Transformation to R, T, Z and picking at these components

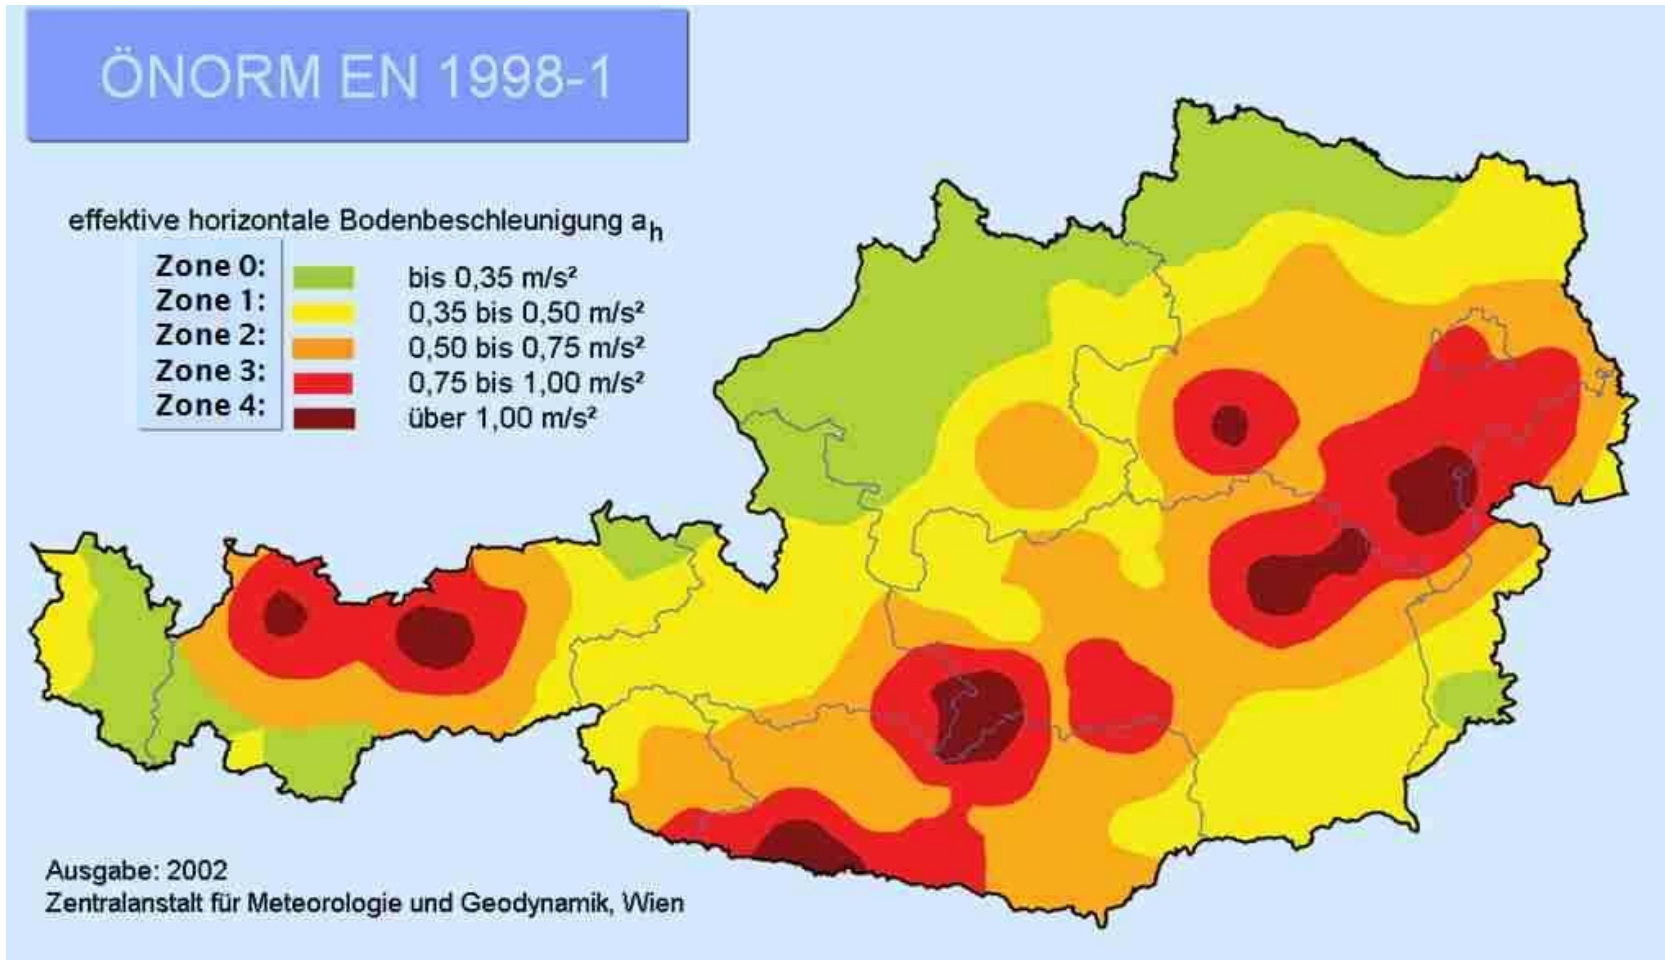

Existing

- Store focal parameters (db)
- Display beach ball (dbevents)

Outlook and further steps

- Parameter exchange between Antelope and the new stacking code
- Rewrite stacking code in Python 2.7
- Parameter calibration and sensitivity analysis of stacking method
- Systematic comparison with own manual solutions and that of SLU, OGS, GFZ for stronger events
- Definition of MI threshold for reliable solutions and re-computation for past events
- Interpretation with mapped faults, velocities and stress field

This Hazard was based on our earthquake catalogue including events from historic earthquake studies and produced in 2002.
